Background

GERD and Bronchial Responsiveness (BHR): Correlation and effect of Fundoplication

GERD and Bronchial Responsiveness (BHR) are both chronic conditions that can affect the respiratory system. Fundoplication, a surgical procedure that strengthens the lower esophageal sphincter, has been studied for its effects on BHR and GERD. This study aimed to investigate the correlation and effects of Fundoplication on GERD and BHR.

Methods

The methods section details the research design, participants, and procedures used in the study. It includes information about the selection of participants, the intervention (Fundoplication), and the outcome measures (GERD symptoms, BHR).

Results

The results section presents the findings of the study. It includes statistical analyses, comparisons between groups, and the impact of Fundoplication on GERD and BHR.

Conclusions

The conclusions section summarizes the findings and their implications. It discusses the significance of the results and suggests potential areas for future research.

Additional information: This image contains data visualizations, such as graphs and charts, which represent the study's results. The images are used to illustrate trends and correlations between GERD and BHR post-Fundoplication.
